

Scripts and Modules

Exercises

Week 5

Prior to attempting these exercises ensure you have read the lecture notes and/or viewed the video, and followed the practical. You may wish to use the Python interpreter in interactive mode to help work out the solutions to some of the questions.

Download and store this document within your own filespace, so the contents can be edited. You will be able to refer to it during the test in Week 6.

Enter your answers directly into the highlighted boxes.

For more information about the module delivery, assessment and feedback please refer to the module within the MyBeckett portal.

When a Python program is stored within a text file (i.e. a *script*), what suffix should be used for the filename?

Answer:

```
.py
```

Is it necessary to use a special Integrated Development Environment (IDE) to write Python code in text files?

Answer:

No, it is not necessary to use a special Integrated Development Environment (IDE) to write Python code in text files. You can use any text editor to write Python code, such as Notepad, Sublime Text, Atom, Vim, Emacs, and many more 12. However, using an IDE can make coding easier and more efficient by providing features such as syntax highlighting, code completion, debugging, version control, and more 12. Some popular Python IDEs include PyCharm, Spyder, Visual Studio Code, and Thonny

When a *script* is executed from a file, are the results of evaluating expressions automatically displayed on the screen without the need of a `print()` function call?

Answer:

No, the results of evaluating expressions are not automatically displayed on the screen when a script is executed from a file. You need to use the `print()` function to display the results on the screen.

What command would need to be typed in an operating system terminal window in order to execute a Python script called `PrintNames.py`?

Answer:

```
python PrintNames.py
```

What command would need to be typed in a terminal in order to pass the values "John", "Eric", "Graham" as *command line arguments* to the `PrintNames.py` script?

Answer:

```
python PrintNames.py "John" "Eric" "Graham"
```

When a Python script wishes to access *command line arguments*, what **module** needs to be imported?

Answer:

Sys module

What is the data-type of the `sys.argv` variable?

Answer:

List data type

What is stored within the first element of the `sys.argv` variable?

Answer:

the name of the program itself.

Use a text editor to write the *script* called `PrintNames.py`. This should display any *command line arguments* that were passed during execution.

Once complete, place your solution in the answer box below.

Answer:

```
import sys
```

```
def main():
```

```
    args = sys.argv[1:]
```

```
    for arg in args:
```

```
        print(arg)
```

Output:

```
C:\Users\Pawan Adhikari\Desktop>python PrintNames.py a b c
```

```
a
```

```
b
```

```
c
```

Improve the solution so it uses an `if` statement to check that at least one name was passed, or otherwise print a message saying “no names provided”. Place your improved solution in the answer box below.

Answer:

```
import sys
```

```
def main():
```

```
    names = sys.argv[1:]
```

```
    if len(names) == 0:
```

```
        print("No names provided")
```

```
    else:
```

```
        for name in names:
```

```
            print("Name provides is", name)
```

Output:

```
C:\Users\Pawan Adhikari\Desktop>python PrintNames.py Pawan
```

```
Name provides is Pawan
```

```
C:\Users\Pawan Adhikari\Desktop>python PrintNames.py
```

```
No names provided
```

When using an import statement it is possible to provide an *alias* that can be used as an alternative name to access module content.

Write an **import** statement that imports the whole of the `sys` module, and renames it to `my_system`.

Answer:

```
import sys as my_system
```

Write a **from..import** statement that imports only the `math.floor` function, and renames it to `lower`

Answer:

```
from math import floor as lower
```

What is stored in a *symbol-table*?

Answer:

```
Name, type, memory location of identifiers of a program
```

Why is the following type of import statement generally not recommended?

```
from math import *
```

Answer:

```
This can cause conflicts and confusion while using various modules.
```

When working in *interactive-mode* what convenient function can be used to list all names defined within a module?

Answer:

```
dir()
```

What is the value stored within the `sys.path` variable used for?

Answer:

Path of directories

When a program is being executed as a *script* what value is assigned to the special variable `__name__`?

Answer:

'__main__'

What value is assigned to the `__name__` variable when a program has been imported as a *module*?

Answer:

'__name__' (filename)

Why is it useful for a program to be able to detect whether it is running as a *script*, or whether it has been imported as a *module*?

Answer:

It enables the script to include code that executes specially when run independently, not when imported as module, promoting modularity and code reusability.

Exercises are complete

Save this logbook with your answers. Then ask your tutor to check your responses to each question.
